

Binary Search Trees

- Dictionary Operations:
 - `get(key)`
 - `put(key, value)`
 - `remove(key)`
- Additional operations:
 - `ascend()`
 - `get(index)` (indexed binary search tree)
 - `remove(index)` (indexed binary search tree)

Complexity Of Dictionary Operations `get()`, `put()` and `remove()`

Data Structure	Worst Case	Expected
Hash Table	$O(n)$	$O(1)$
Binary Search Tree	$O(n)$	$O(\log n)$
Balanced Binary Search Tree	$O(\log n)$	$O(\log n)$

n is number of elements in dictionary

Complexity Of Other Operations `ascend()`, `get(index)`, `remove(index)`

Data Structure	ascend	get and remove
Hash Table	$O(D + n \log n)$	$O(D + n \log n)$
Indexed BST	$O(n)$	$O(n)$
Indexed Balanced BST	$O(n)$	$O(\log n)$

D is number of buckets

Definition Of Binary Search Tree

- A binary tree.
- Each node has a `(key, value)` pair.
- For every node x , all keys in the left subtree of x are smaller than that in x .
- For every node x , all keys in the right subtree of x are greater than that in x .

Example Binary Search Tree

Only keys are shown.

The Operation ascend()

Do an inorder traversal. $O(n)$ time.

The Operation get()

Complexity is $O(\text{height}) = O(n)$, where n is number of nodes/elements.

The Operation put()

Put a pair whose key is 35.

The Operation put()

Put a pair whose key is 7.

The Operation put()

Put a pair whose key is 18.

The Operation put()

Complexity of put() is $O(\text{height})$.

The Operation remove()

Three cases:

- Element is in a leaf.
- Element is in a degree 1 node.
- Element is in a degree 2 node.

Remove From A Leaf

Remove a leaf element. key = 7

Remove From A Leaf (contd.)

Remove a leaf element. key = 35

Remove From A Degree 1 Node

Remove from a degree 1 node. key = 40

Remove From A Degree 1 Node (contd.)

Remove from a degree 1 node. key = 15

Remove From A Degree 2 Node

Remove from a degree 2 node. key = 10

Remove From A Degree 2 Node

Replace with largest key in left subtree (or smallest in right subtree).

Remove From A Degree 2 Node

Replace with largest key in left subtree (or smallest in right subtree).

Remove From A Degree 2 Node

Replace with largest key in left subtree (or smallest in right subtree).

Remove From A Degree 2 Node

Largest key must be in a leaf or degree 1 node.

Another Remove From A Degree 2 Node

Remove from a degree 2 node. key = 20

Remove From A Degree 2 Node

Replace with largest in left subtree.

Remove From A Degree 2 Node

Replace with largest in left subtree.

Remove From A Degree 2 Node

Replace with largest in left subtree.

Remove From A Degree 2 Node

Complexity is $O(\text{height})$.

Indexed Binary Search Tree

- Binary search tree.
- Each node has an additional field.
 - leftSize = number of nodes in its left subtree

Example Indexed Binary Search Tree

leftSize values are in red

leftSize And Rank

Rank of an element is its position in inorder
(inorder = ascending key order).

$[2, 6, 7, 8, 10, 15, 18, 20, 25, 30, 35, 40]$

$\text{rank}(2) = 0$

$\text{rank}(15) = 5$

$\text{rank}(20) = 7$

$\text{leftSize}(x) = \text{rank}(x)$ with respect to elements in
subtree rooted at x

leftSize And Rank

sorted list = $[2, 6, 7, 8, 10, 15, 18, 20, 25, 30, 35, 40]$

get(index) And remove(index)

sorted list = $[2, 6, 7, 8, 10, 15, 18, 20, 25, 30, 35, 40]$

get(index) And remove(index)

- if $\text{index} = x.\text{leftSize}$ desired element is $x.\text{element}$
- if $\text{index} < x.\text{leftSize}$ desired element is index 'th element in left subtree of x
- if $\text{index} > x.\text{leftSize}$ desired element is $(\text{index} - x.\text{leftSize} - 1)$ 'th element in right subtree of x

Applications

(Complexities Are For Balanced Trees)

Best-fit bin packing in $O(n \log n)$ time.

Representing a linear list so that `get(index)`, `add(index, element)`, and `remove(index)` run in $O(\log(\text{list size}))$ time (uses an indexed binary tree, not indexed binary search tree).

Can't use hash tables for either of these applications.

Linear List As Indexed Binary Tree

list = [a,b,c,d,e,f,g,h,i,j,k,l]

add(5,'m')

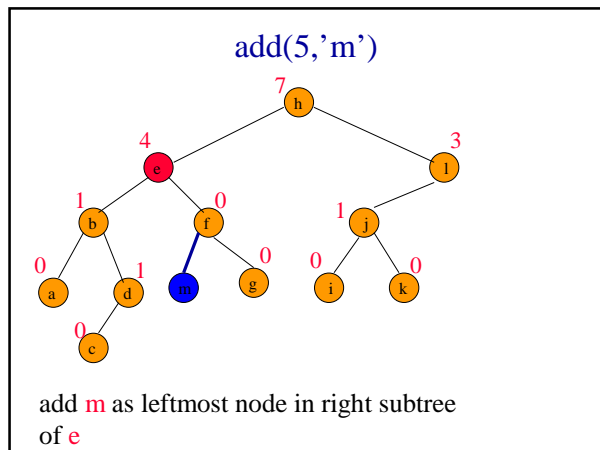

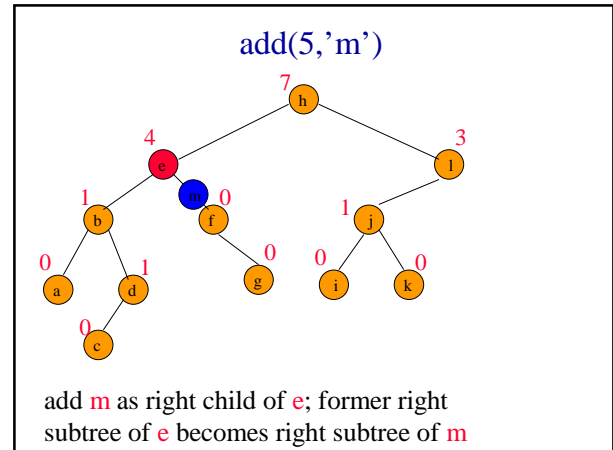

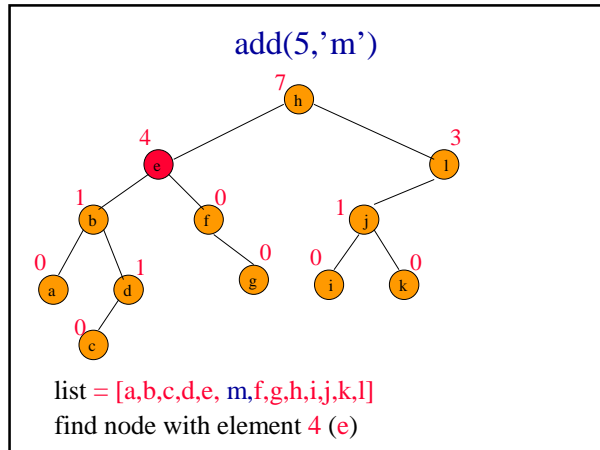

list = [a,b,c,d,e,f,g,h,i,j,k,l]

add(5,'m')

list = [a,b,c,d,e, m,f,g,h,i,j,k,l]

find node with element 4 (e)

- add(5,'m')
- Other possibilities exist.
 - Must update some leftSize values on path from root to new node.
 - Complexity is $O(\text{height})$.
