

## Rank

Rank of an element is its position in ascending key order.

[2,6,7,8,10,15,18,20,25,30,35,40]

$\text{rank}(2) = 0$

$\text{rank}(15) = 5$

$\text{rank}(20) = 7$

## Selection Problem

- Given  $n$  unsorted elements, determine the  $k$ 'th smallest element. That is, determine the element whose rank is  $k-1$ .
- Applications
  - Median score on a test.
    - $k = \text{ceil}(n/2)$ .
  - Median salary of Computer Scientists.
  - Identify people whose salary is in the bottom 10%. First find salary at the 10% rank.

## Selection By Sorting

- Sort the  $n$  elements.
- Pick up the element with desired rank.
- $O(n \log n)$  time.

## Divide-And-Conquer Selection

- Small instance has  $n \leq 1$ . Selection is easy.
- When  $n > 1$ , select a **pivot** element from out of the  $n$  elements.
- Partition the  $n$  elements into 3 groups **left**, **middle** and **right** as is done in quick sort.
- The rank of the **pivot** is the location of the pivot following the partitioning.
- If  $k-1 = \text{rank}(\text{pivot})$ , **pivot** is the desired element.
- If  $k-1 < \text{rank}(\text{pivot})$ , determine the  $k$ 'th smallest element in **left**.
- If  $k-1 > \text{rank}(\text{pivot})$ , determine the  $(k - \text{rank}(\text{pivot}) - 1)$ 'th smallest element in **right**.

## D&C Selection Example

Find  $k$ th element of:

a 

3	2	8	0	11	10	1	2	9	7	1
---	---	---	---	----	----	---	---	---	---	---

Use 3 as the pivot and partition.

a 

1	2	1	0	2	3	10	11	9	7	8
---	---	---	---	---	---	----	----	---	---	---

$\text{rank}(\text{pivot}) = 5$ . So  $\text{pivot}$  is the 6'th smallest element.

## D&C Selection Example

a 

1	2	1	0	2	3	10	11	9	7	8
---	---	---	---	---	---	----	----	---	---	---

- If  $k = 6$  ( $k-1 = \text{rank}(\text{pivot})$ ),  $\text{pivot}$  is the element we seek.
- If  $k < 6$  ( $k-1 < \text{rank}(\text{pivot})$ ), find  $k$ 'th smallest element in  $\text{left}$  partition.
- If  $k > 6$  ( $k-1 > \text{rank}(\text{pivot})$ ), find  $(k - \text{rank}(\text{pivot}) - 1)$ 'th smallest element in  $\text{right}$  partition.

## Time Complexity

- Worst case arises when the partition to be searched always has all but the **pivot**.
  - $O(n^2)$
- Expected performance is  $O(n)$ .
- Worst case becomes  $O(n)$  when the **pivot** is chosen carefully.
  - Partition into  $n/9$  groups with 9 elements each (last group may have a few more)
  - Find the median element in each group.
  - **pivot** is the median of the group medians.
  - This median is found using **select** recursively.

## Closest Pair Of Points

- Given  $n$  points in 2D, find the pair that are closest.

## Applications

- We plan to drill holes in a metal sheet.
- If the holes are too close, the sheet will tear during drilling.
- Verify that no two holes are closer than a threshold distance (e.g., holes are at least **1 inch** apart).

## Air Traffic Control

- 3D -- Locations of airplanes flying in the neighborhood of a busy airport are known.
- Want to be sure that no two planes get closer than a given threshold distance.

## Simple Solution

- For each of the  $n(n-1)/2$  pairs of points, determine the distance between the points in the pair.
- Determine the pair with the minimum distance.
- $O(n^2)$  time.

## Divide-And-Conquer Solution

- When  $n$  is small, use simple solution.
- When  $n$  is large
  - Divide the point set into two roughly equal parts  $A$  and  $B$ .
  - Determine the closest pair of points in  $A$ .
  - Determine the closest pair of points in  $B$ .
  - Determine the closest pair of points such that one point is in  $A$  and the other in  $B$ .
  - From the three closest pairs computed, select the one with least distance.

## Example

- Divide so that points in **A** have **x**-coordinate  $\leq$  that of points in **B**.

## Example

- Find closest pair in **A**.
- Let  $d_1$  be the distance between the points in this pair.

## Example

- Find closest pair in **B**.
- Let  $d_2$  be the distance between the points in this pair.

## Example

- Let  $d = \min\{d_1, d_2\}$ .
- Is there a pair with one point in **A**, the other in **B** and distance  $< d$ ?

## Example

- Candidates lie within  $d$  of the dividing line.
- Call these regions  $R_A$  and  $R_B$ , respectively.

## Example

- Let  $q$  be a point in  $R_A$ .
- $q$  need be paired only with those points in  $R_B$  that are within  $d$  of  $q$ .

## Example

- Points that are to be paired with  $q$  are in a  $d \times 2d$  rectangle of  $R_B$  (comparing region of  $q$ ).
- Points in this rectangle are at least  $d$  apart.

## Example

- So the comparing region of  $q$  has at most 6 points.
- So number of pairs to check is  $\leq 6 |R_A| = O(n)$ .

## Time Complexity

- Create a sorted by **x**-coordinate list of points.
  - $O(n \log n)$  time.
- Create a sorted by **y**-coordinate list of points.
  - $O(n \log n)$  time.
- Using these two lists, the required pairs of points from  $R_A$  and  $R_B$  can be constructed in  $O(n)$  time.
- Let  $n < 4$  define a **small** instance.

## Time Complexity

- Let  $t(n)$  be the time to find the closest pair (excluding the time to create the two sorted lists).
- $t(n) = c$ ,  $n < 4$ , where  $c$  is a constant.
- When  $n \geq 4$ ,
$$t(n) = t(\text{ceil}(n/2)) + t(\text{floor}(n/2)) + an,$$
where  $a$  is a constant.
- To solve the recurrence, assume  $n$  is a power of 2 and use repeated substitution.
- $t(n) = O(n \log n)$ .
