Matrix Multiplication Chains

- Determine the best way to compute the matrix product M₁x M₂ x M₃ x ... x M_a.
- Let the dimensions of M_i be $r_i \times r_{i+1}$.
- q-1 matrix multiplications are to be done.
- Decide the matrices involved in each of these multiplications.

Decision Sequence

- $M_1 \times M_2 \times M_3 \times ... \times M_q$
- Determine the q-1 matrix products in reverse order.
 - What is the last multiplication?
 - What is the next to last multiplication?
 - And so on.

Problem State

- $M_1 x M_2 x M_3 x ... x M_q$
- The matrices involved in each multiplication are a contiguous subset of the given q matrices.
- The problem state is given by a set of pairs of the form (i, j), i <= j.
 - The pair (i,j) denotes a problem in which the matrix product M_ix M_{i+1} x ... x M_i is to be computed.
 - The initial state is (1,q).
 - If the last matrix product is $(M_1 x \ M_2 \ x \ \dots x \ M_k) \ x \ (M_{k+1} x \ M_{k+2} \ x \ \dots x \ M_q)$, the state becomes $\{(1,k),(k+1,q)\}$.

Verify Principle Of Optimality

- Let $M_{ii} = M_i \times M_{i+1} \times ... \times M_i$, $i \le j$.
- Suppose that the last multiplication in the best way to compute M_{ij} is $M_{ik} \times M_{k+1,j}$ for some $k, i \le k \le j$.
- Irrespective of what k is, a best computation of M_{ij}in which the last product is M_{ik}x M_{k+1,j} has the property that M_{ik}and M_{k+1,j} are computed in the best possible way.
- So the principle of optimality holds and dynamic programming may be applied.

Recurrence Equations

- Let c(i,j) be the cost of an optimal (best) way to compute M_{ii}, i <= j.
- c(1,q) is the cost of the best way to multiply the given q matrices.
- Let kay(i,j) = k be such that the last product in the optimal computation of M_{ij} is M_{ik}x M_{k+l,i}.
- c(i,i) = 0, $1 \le i \le q$. $(M_{ii} = M_i)$
- $c(i,i+1) = r_i r_{i+1} r_{i+2}$, $1 \le i \le q$. $(M_{ii+1} = M_i x M_{i+1})$
- kay(i,i+1) = i.

$$c(i, i+s), 1 < s < q$$

- The last multiplication in the best way to compute $M_{i,i+s}$ is $M_{ik}x$ $M_{k+1,i+s}$ for some k, $i \le k < i+s$.
- If we knew k, we could claim:

$$c(i,i+s) = c(i,k) + c(k+1,i+s) + r_i r_{k+1} r_{i+s+1}$$

- Since i <= k < i+s, we can claim
 c(i,i+s) = min{c(i,k) + c(k+1,i+s) + r_ir_{k+1}r_{i+s+1}}, where
 the min is taken over i <= k < i+s.
- kay(i,i+s) is the k that yields above min.

Recurrence Equations

- c(i,i+s) = $\min_{i \le k \le i+s} \{c(i,k) + c(k+1,i+s) + r_i r_{k+1} r_{i+s+1} \}$
- c(*,*) terms on right side involve fewer matrices than does the c(*,*) term on the left side.
- So compute in the order s = 2, 3, ..., q-1.

A Recursive Implementation

- See text for recursive codes.
- Code that does not avoid recomputation of already computed c(i,j)s runs in Omega(2q)
- Code that does not recompute already computed c(i,j)s runs in $O(q^3)$ time.
- Implement nonrecursively for best worst-case efficiency.

Example

- q = 4, $(10 \times 1) * (1 \times 10) * (10 \times 1) * (1 \times 10)$
- $\mathbf{r} = [\mathbf{r}_1, \mathbf{r}_2, \mathbf{r}_3, \mathbf{r}_4, \mathbf{r}_5] = [10, 1, 10, 1, 10]$

c(i,j), $i \le j$

 $kay(i,j), i \le j$

$$s = 0$$

c(i,i) and kay(i,i), $1 \le i \le 4$ are to be computed.

 $c(i,j), i \le j$

kay(i,j), $i \le j$

$$s = 1$$

c(i,i+1) and kay(i,i+1), $1 \le i \le 3$ are to be computed.

 $c(i,j), i \le j$

 $kay(i,j), i \le j$

s = 1

- $c(i,i+1) = r_i r_{i+1} r_{i+2}$, $1 \le i < q$. $(M_{ii+1} = M_i x M_{i+1})$
- kay(i,i+1) = i.
- $\mathbf{r} = [\mathbf{r}_1, \mathbf{r}_2, \mathbf{r}_3, \mathbf{r}_4, \mathbf{r}_5] = [10, 1, 10, 1, 10]$

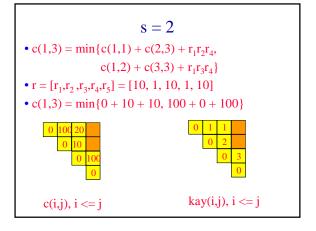

c(i,j), $i \le j$

 $kay(i,j), i \le j$

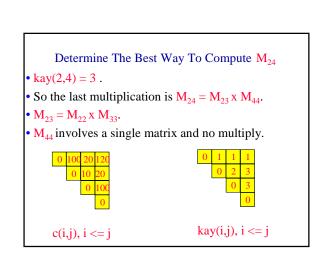

$$\begin{split} s &= 2 \\ \bullet c(i,i+2) &= \min\{c(i,i) + c(i+1,i+2) + r_i r_{i+1} r_{i+3}, \\ c(i,i+1) + c(i+2,i+2) + r_i r_{i+2} r_{i+3}\} \\ \bullet r &= [r_1,r_2,r_3,r_4,r_5] = [10, 1, 10, 1, 10] \\ \hline \\ 0 &= 0 \\ \hline 0 &= 0 \\ \hline 0 &= 0 \\ \hline c(i,j), i <= j \\ \end{split}$$

$$\begin{split} s &= 2 \\ \bullet c(2,4) &= \min\{c(2,2) + c(3,4) + r_2r_3r_5, \\ c(2,3) + c(4,4) + r_2r_4r_5\} \\ \bullet r &= [r_1,r_2,r_3,r_4,r_5] = [10,1,10,1,10] \\ \bullet c(2,4) &= \min\{0 + 100 + 100,10 + 0 + 10\} \\ \hline 0 & 100 & 20 \\ \hline 0 & 10 & 20 \\ \hline 0 & 10 & 20 \\ \hline 0 & 10 & 2 & 3 \\ \hline 0 & 0 & 3 \\ \hline 0 & c(i,j),i <= j \end{split}$$

The Best Way To Compute M₁₄

- The multiplications (in reverse order) are:
 - $M_{14} = M_{11} \times M_{24}$
 - $M_{24} = M_{23} \times M_{44}$
 - $M_{23} = M_{22} \times M_{33}$

Time Complexity

- $c(i,j), i \le j$
- O(q²) c(i,j) values are to be computed, where q is the number of matrices.
- $\bullet \ c(i,i+s) = min_{|i| <=|k| < |i+s|} \{c(i,k) + c(k+1,i+s) + r_i r_{k+1} r_{i+s+1} \}.$
- Each c(i,j) is the min of O(q) terms.
- Each of these terms is computed in O(1) time.
- So all c(i,j) are computed in $O(q^3)$ time.

Time Complexity

$$kay(i,j), i \le j$$

- The traceback takes O(1) time to determine each matrix product that is to be done.
- q-1 products are to be done.
- Traceback time is O(q).
