

PRESENTATION PIE

Social network parameters

CONNECTIVITY

- Degree distribution of the node
- Binomial, Poisson, Geometric, power law distribution

GEODESIC DISTANCE

- Minimum No of links that need to be used along some n/w path to connect nodes i and j
- Based on which average network distance is calculated

CLUSTERING

- Defined as the fraction of pairs of neighbors of a node that are themselves neighbors
- Informational & strategic implications in networks

COHESIVENESS

- How shielded is the set of nodes from outside influence
- Explains the concept of exogamous links

BETWEENNESS

- Measure of the importance of the node in bridging the connection between other nodes.

SOCIAL NETWORKS

- ✓ A feedback network is one where active nodes or agents send tokens or communications through their network to help locate potential partners for new ties.
- ✓ When a previously unconnected partner is located given constraints of distance a new tie is formed, creating a feedback loop.
- ✓ Failing to locate a partner within the network, the active node engaged in partner selection recruits a new partner from outside the existing network and forms a tie.
- ✓ Three parameters (alpha, beta & Gamma) are used to govern network formation in this probabilistic generative model. These govern levels of node activity, distance decay in how soon network traversal fails to find a partner, and the extent to which local hubs are used in network traversal.
- ✓ The model provides an explanation for how hubs are formed in networks, how well-traveled edges are formed, how cycles and cohesion are formed, and how other features of real-world networks may result from different combinations of three basic network parameters.

- ✓ Like many real-world networks, feedback networks modeled by this process evolve large networks with cohesive ties (social circles). In this way, small worlds with cohesive subgroups and relatively short distances may be generated, scale-free networks may be generated, or a variety of other network topologies may be generated.
- ✓ Captures the small world phenomenon of strangers being linked by a mutual acquaintance
- ✓ Essential Features:
 - A small average shortest path length
 - A large clustering coefficient

- ✓ Small world network model does not account for the heterogeneity encountered in many real world networks.
- ✓ A **scale-free network** is a network whose degree distribution follows a power law.
- ✓ The two essential features:
 - The mechanism of **preferential attachment** has been proposed as an underlying generative model to explain power law degree distributions .
 - **Growth** The network is formed, becoming even larger, through the successive arrival of new nodes that, upon entry link to some of the pre existing nodes.

(a) Random network

(b) Scale-free network

“Birds of a feather flock together”

- ❖ The scientific word for this psychological phenomenon is “**HOMOPHILY**”.
- ❖ **Homophily** (i.e., love of the same) is the tendency of individuals to associate and bond with similar others .
- ❖ Homophily is the principle that a contact between similar people occurs at a higher rate than among dissimilar people.
- ❖ McPherson, Smith-Lovin and Cook (2001) cite over one hundred studies that have observed homophily in some form or another. These include age, gender, class, organizational role ,etc.
- ❖ Homophily Distinction:
 - **Baseline homophily** :homophily effects that are created by the demography of the potential tie pool
 - **Inbreeding homophily** :homophily measured as explicitly over and above the opportunity set .

PRESENTATION PIE

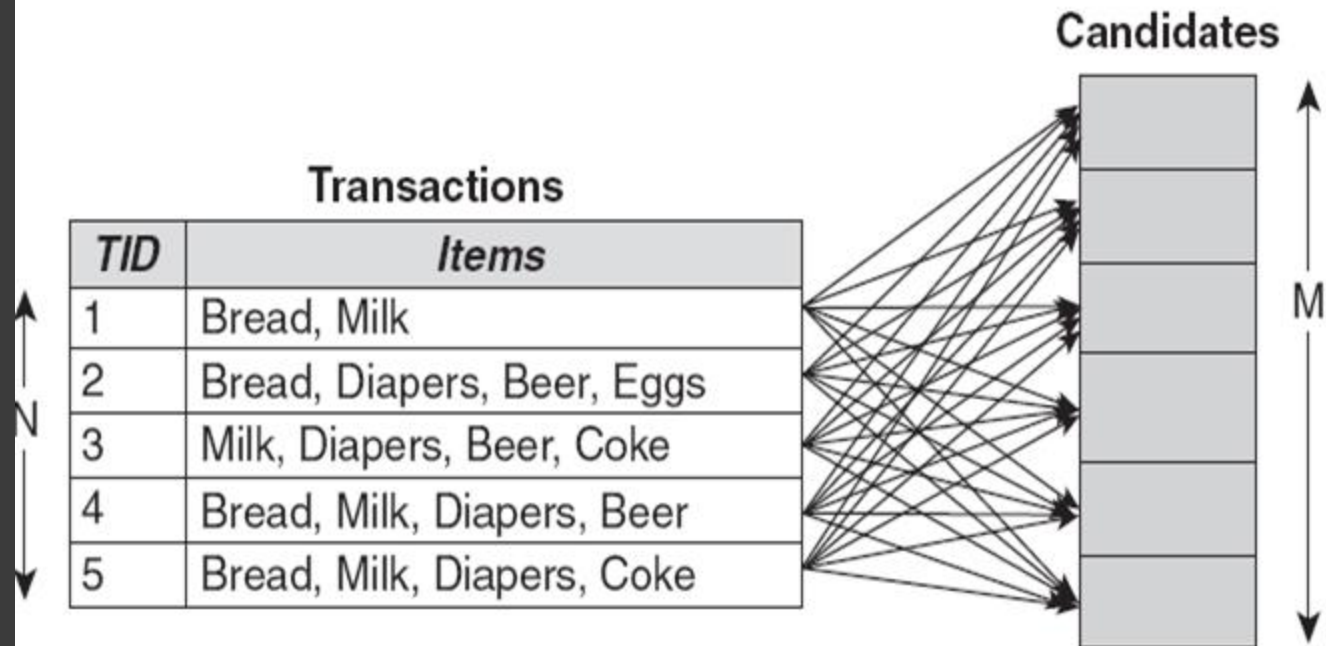

ASSOCIATION ANALYSIS

- It is a methodology used for discovering interesting relationships hidden in large datasets.
- Example Algorithms : Apriori Algorithm, FP-Growth Algorithm

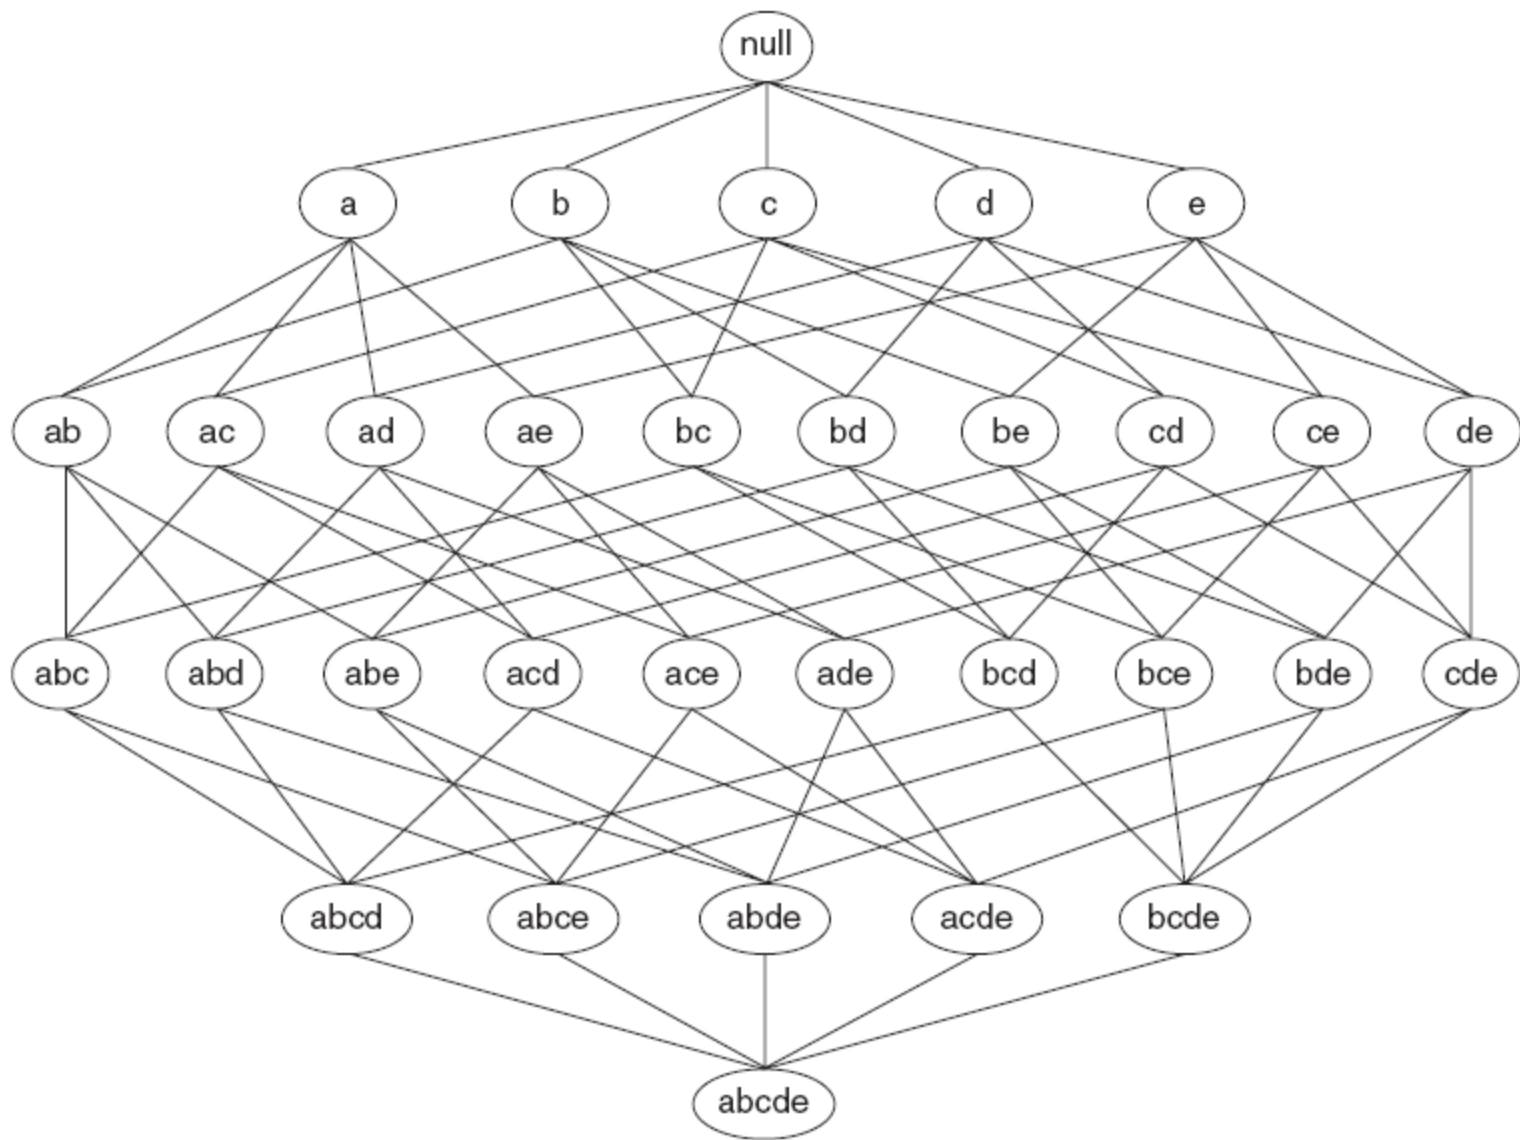

An example of market basket transactions.

<i>TID</i>	Items
1	{Bread, Milk}
2	{Bread, Diapers, Beer, Eggs}
3	{Milk, Diapers, Beer, Cola}
4	{Bread, Milk, Diapers, Beer}
5	{Bread, Milk, Diapers, Cola}

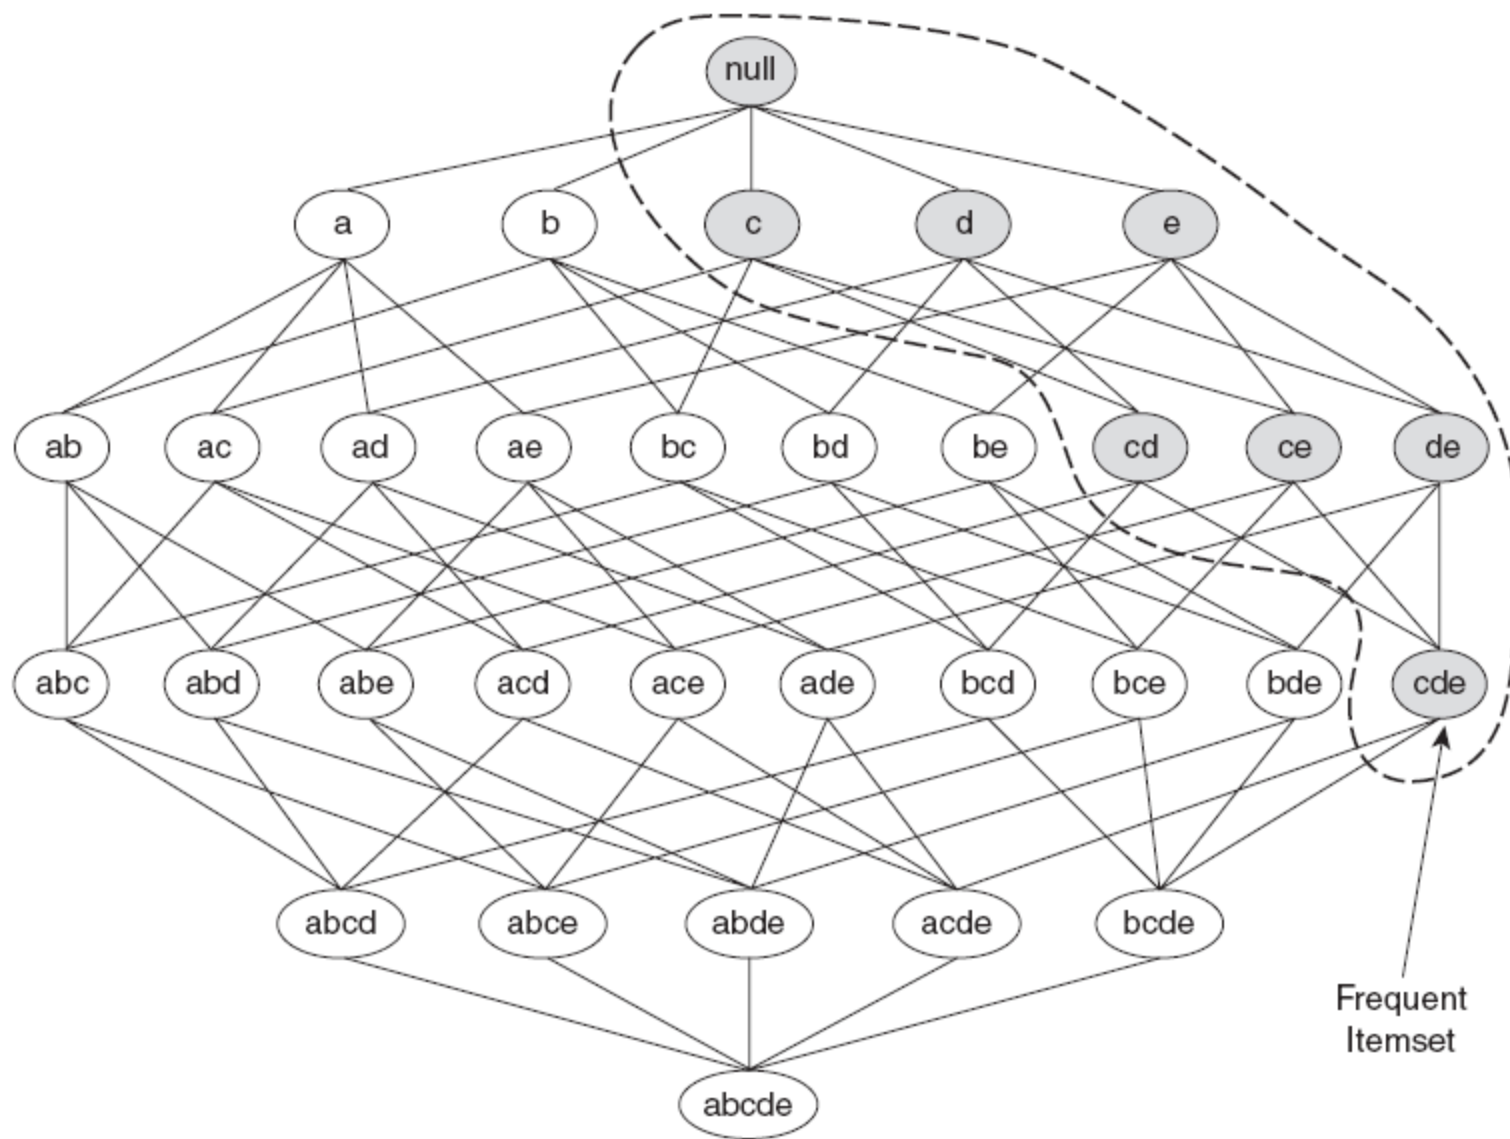

Frequent Itemset Generation

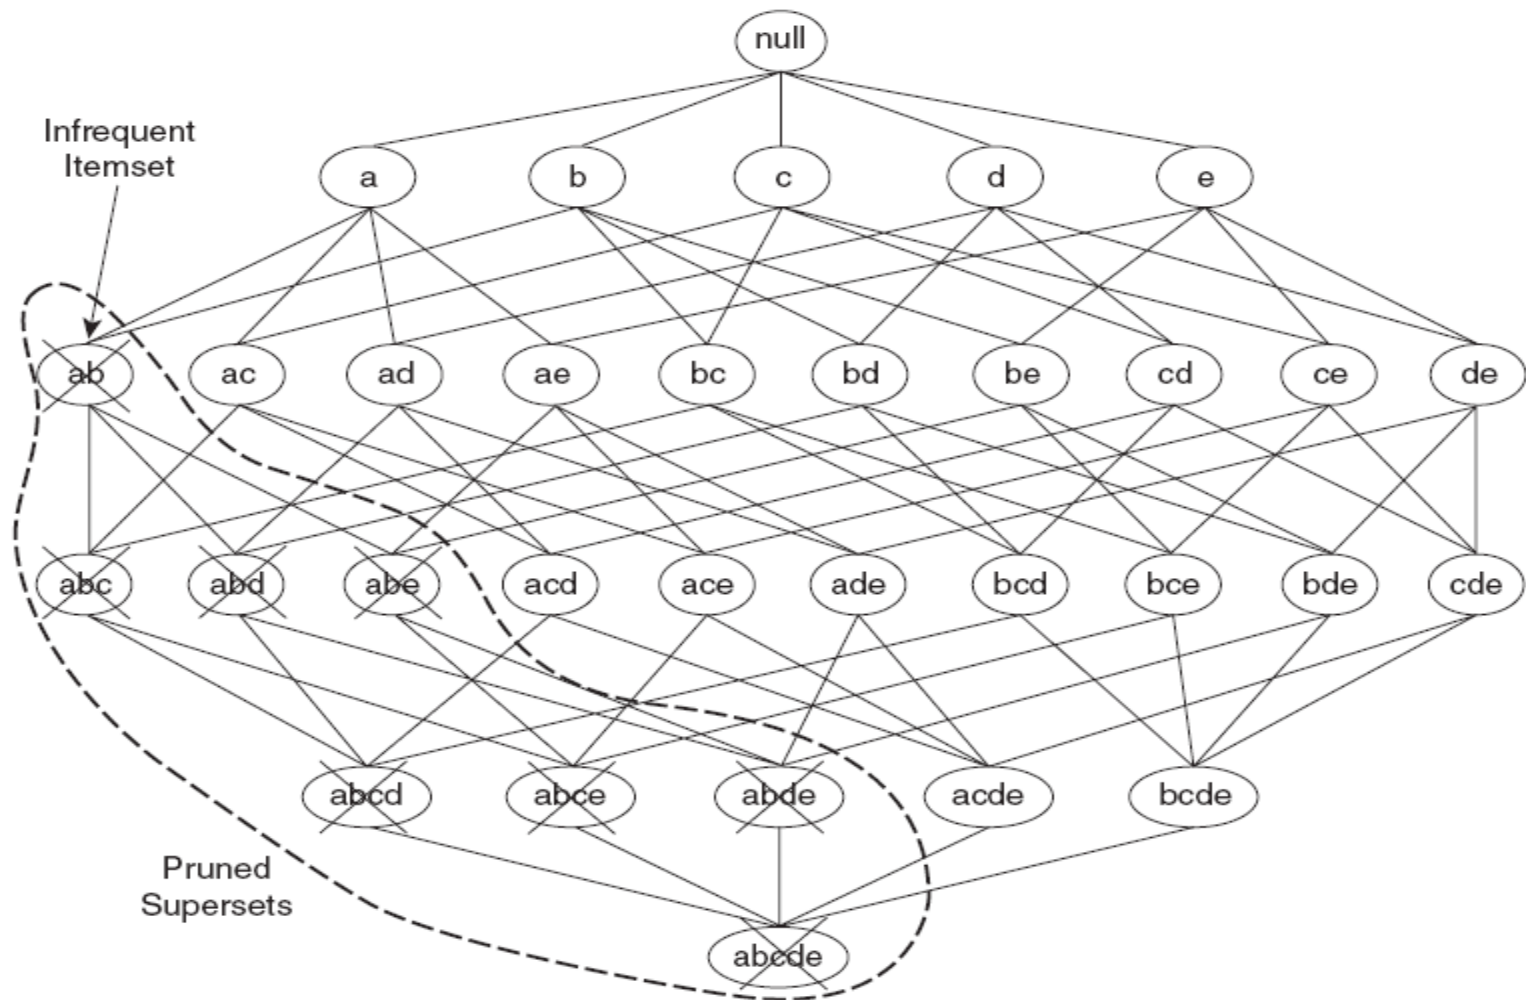

Counting the support of candidate itemsets.

An itemset lattice.

An illustration of the *Apriori* principle.

anti-monotone property

$$\forall X, Y \in J : (X \subseteq Y) \longrightarrow f(Y) \leq f(X),$$

SUPPORT-The measure of how often the collection of items in an association occur together as a percentage of all the transactions.

$$\text{Support, } s(X \longrightarrow Y) = \frac{\sigma(X \cup Y)}{N};$$

CONFIDENCE-Confidence of rule "B given A" is a measure of how much more likely it is that B occurs when A has occurred. Statisticians refer to this as the conditional probability of B given A.

$$\text{Confidence, } c(X \longrightarrow Y) = \frac{\sigma(X \cup Y)}{\sigma(X)}.$$

Candidate
1-Itemsets

Item	Count
Beer	3
Bread	4
Cola	2
Diapers	4
Milk	4
Eggs	1

Minimum support count = 3

Candidate
2-Itemsets

Itemset	Count
{Beer, Bread}	2
{Beer, Diapers}	3
{Beer, Milk}	2
{Bread, Diapers}	3
{Bread, Milk}	3
{Diapers, Milk}	3

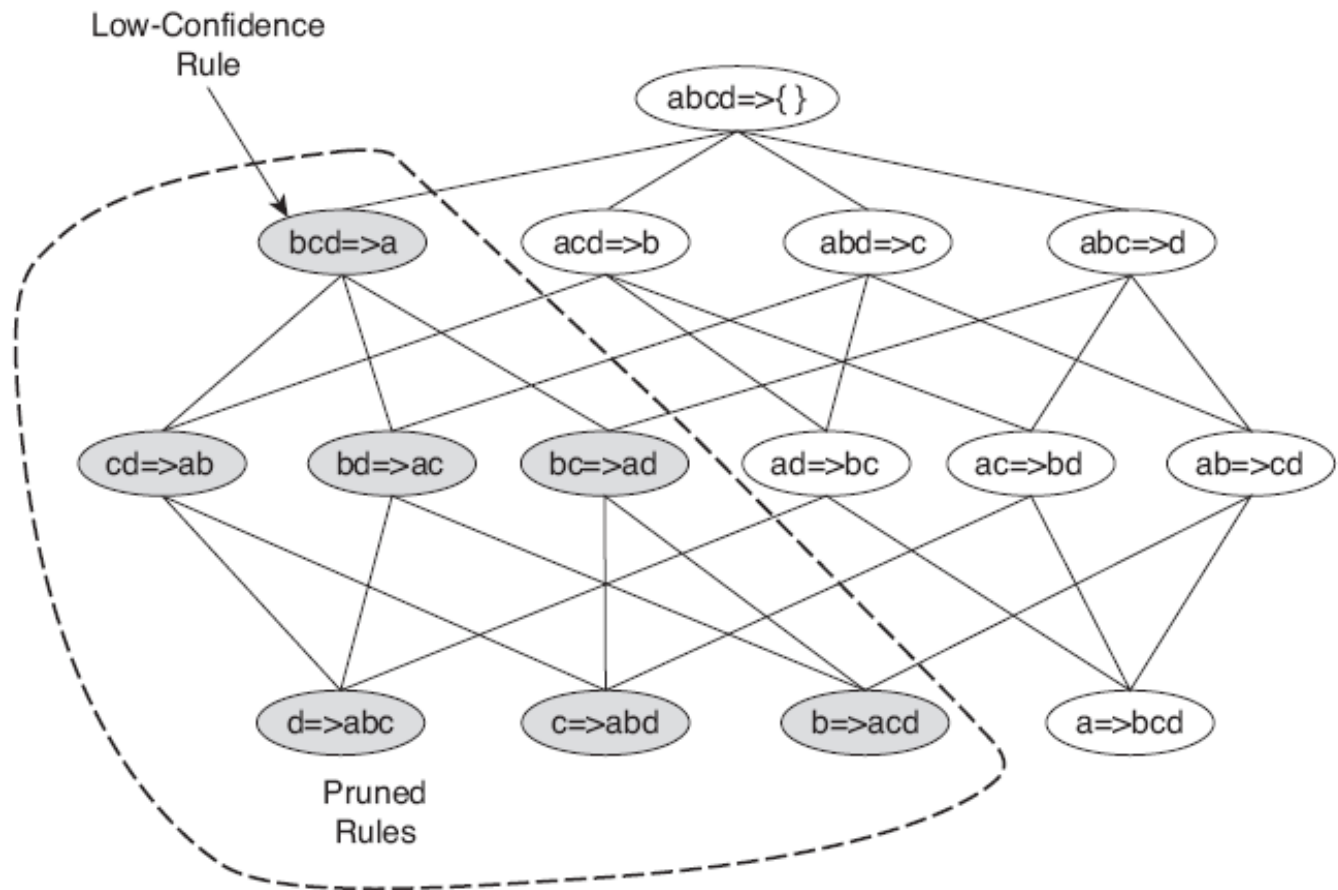

Itemsets removed
because of low
support

Candidate
3-Itemsets

Itemset	Count
{Bread, Diapers, Milk}	3

Illustration of frequent itemset generation using the *Apriori* algorithm.

Rule Generation

Pruning of association rules using the confidence measure.
